Create Schemas and Models

Firstly, configure the Schemas for MongoDB database, to store the data in such a pattern. Use the data from the ER diagrams to create the schemas.

The Schemas for this application look alike to the one provided below.

1. **UserSchema:** Mongoose model defining the schema for user data including email, password, and other profile info.

```
const mongoose = require('mongoose');

const connectDB = async() => {
    try {
        await mongoose.connect(process.env.MONGO_URI);
        console.log("MongoDB Connected")
    } catch (error) {
        console.error(error.message);
        process.exit(1);
    }
}

module.exports = connectDB;
```

2. **SuggestionSchema:**Mongoose model defining the schema for storing nutrition suggestions in the database.

```
const mongoose = require("mongoose");

const foodSchema =  mongoose.Schema({
    name: { type: String, required: true },
    grams: { type: String, required: true }
});

const suggestionSchema = new mongoose.Schema({

    userId: { type: mongoose.Schema.Types.ObjectId, ref: 'User' },
    userName: { type: String },

    age: { type: Number, required: true },
    height: { type: Number, required: true },
    weight: { type: Number, required: true },
    bmi: { type: String, required: true },

    suggestion: { type: String, required: true },
    timing: { type: String, required: true },
    walk: { type: String },

    foods: [foodSchema],
    calorieIntake: { type: Number, required: true },
    carbohydrateNeeds: { type: String },
    proteinNeeds: { type: String },

    weightGain: { type: Number, required: true },

    date: {
        type: String,
        default: () => new Date().toLocaleDateString('hi-IN')
    }
});

const Suggestion = mongoose.model('Suggestion', suggestionSchema);

module.exports = Suggestion;
```
